

Lecture 03 P.O.D.

What are the heat transfer characteristics of the SNAP-27 RTGs used in the lunar missions?

RTG: Radioisotopic Thermoelectric Generator

- Uses thermoelectric (Seebeck) effect to directly convert a temp. gradient into electricity
- Not very efficient, (about 10% max) but no moving parts!
- Uses radioisotopic (Pu238 or other α emitters - low shielding requirement) to produce heat, + sink to produce gradient

- design:

(2)

3 Questions:

- 1) What is the "effective temp." of the radiators?
- 2) What is the effective thermal conductivity of the annular RTG?
- 3) What is the temperature of the central void?

Some numbers:

$$L = 35 \text{ cm (fuel length)} \quad 41.9 \text{ in (cannister length)}$$

$$D = 6.4 \text{ cm (cannister diameter)}$$

$$3735 \text{ g fuel, } 10.3 \text{ g/cm}^3 \text{ particle density (mass density)}$$

$$2.6 \text{ W/cm}^3 \text{ power density}$$

$$0.40 \text{ W/g}$$

$$1480 \text{ W thermal energy volume} = 569 \text{ cm}^3$$

$$(\text{packing fraction} = \left(\frac{3735}{569} \right) / 10.3 = \frac{6.56}{10.3} \approx 0.64)$$

$$K_{\text{fuel}} = 0.62 \frac{\text{Btu}}{\text{hr ft}^2 \text{ } ^\circ\text{F}} = 1.07 \frac{\text{W}}{\text{m}^2 \text{ } ^\circ\text{K}}$$

(3)

If the volume is 569 cm^3 , length is 35 cm ,
 OD is 6.4 cm , what is ID?

$$\pi \left(\frac{\text{OD}}{2} \right)^2 - \pi \left(\frac{\text{ID}}{2} \right)^2 = \frac{569}{35}$$

$$\text{OD}^2 - \text{ID}^2 = \frac{4}{\pi} \frac{569}{35} = 20.7 \text{ cm}^2$$

$$\therefore \text{ID} = 4.5 \text{ cm}$$

So thickness is just 0.95 cm (pretty thin)

The RTG layer has an inner diameter of 6.4 cm . From the picture, the outer diameter is about $3 \times$ this, or 19.2 cm

Thus for RTG, $R_i/R_o \approx 3$

For a cylindrical geometry:

$$\frac{Q}{2\pi L} \frac{\ln(R_i/R_o)}{k} = T_i - T_o$$

From the report, $Q = 1480 \text{ W}$

$$T_i = 866^\circ \text{K} \quad T_o = 547^\circ \text{K} \quad \therefore T_i - T_o = 319^\circ \text{K}$$

(4)

$$\therefore k_{\text{RTG}} = \frac{1480 \text{ W}}{2\pi (0.42 \text{ m})} \frac{\ln(3)}{319 \text{ K}} = \frac{1.93 \text{ W}}{\text{m} \cdot \text{K}}$$

This is about the thermal conductivity of porcelain (a bit higher)

It is the conductivity of silicon-germanium semiconductors often used in RTGs. ($1-2 \frac{\text{W}}{\text{m} \cdot \text{K}}$)

How much hotter is the inside of the fuel layer than the outside?

- thickness = 0.95 cm \ll 3.2 cm outer radius

- approximate w/ a slab (flat earth limit)
otherwise would get ~~logarithm terms~~ ~~logarithm terms~~!

$$\begin{array}{c} \sim T = T_i \\ \overbrace{\quad \updownarrow h \quad} \\ \underbrace{\quad \quad \quad} \\ T = T_o \text{ (unknown)} \end{array}$$

$$0 = k \frac{\partial^2 T}{\partial y^2} + \dot{S}$$

5

$$y^* = \frac{y}{h}, \quad T^* = \frac{(T - T_1)}{\Delta T_c}$$

$$T^* \Big|_{y^*=1} = 0 \quad \frac{\partial T^*}{\partial y^*} \Big|_{y^*=0} = 0 \quad (\text{insulated void})$$

$$\frac{k \Delta T_c}{h^2} \frac{\partial^2 T^*}{\partial y^{*2}} = -\dot{S}$$

$$\frac{\partial^2 T^*}{\partial y^{*2}} = - \left[\frac{\dot{S} h^2}{k \Delta T_c} \right]$$

$$\text{So } \Delta T_c = \frac{\dot{S} h^2}{k}$$

$$\dot{S} = 2.6 \frac{\text{W}}{\text{cm}^3} \quad h = 0.95 \text{ cm} \quad k = 1.07 \frac{\text{W}}{\text{m}^2 \text{K}} = 0.01 \frac{\text{W}}{\text{cm}^2 \text{K}}$$

$$\therefore \Delta T_c = \frac{(2.6)(0.95)^2}{0.0107} = 219^\circ \text{K}$$

What is $T^* \Big|_{y^*=0}$?

$$T^* = -\frac{1}{2} y^{*2} + A y^* + B$$

$$\frac{\partial T^*}{\partial y^*} \Big|_{y^*=0} = 0 \therefore A = 0 \quad T^* \Big|_{y^*=1} = 0 \therefore B = \frac{1}{2}$$

so $T^* \Big|_{y^*=0} = \frac{1}{2}$ and the inside is 110°K hotter than outside!

(6)

Finally, look at radiative cooling

$$q = \sigma T^4$$

\hookrightarrow Stefan-Boltzmann Constant

$$\sigma = 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \text{K}}$$

The outside is 547°K

If we have a length of 0.4 m and

$$q = \frac{Q}{(L)\pi D} = \frac{1486 - 63.5 \text{ W}}{(0.4 \text{ m})\pi D} = 5.67 \times 10^{-8} (547)^4$$

(63.5 W was removed
by production)

$$\therefore D = \frac{1416}{(0.4)(\pi)(5.67 \times 10^{-8})(547)^4} = 0.22 \text{ m}$$

or 22 cm

This is a bit small (more like ~ 50 cm from picture) because it ignores back radiation and a lot of the fans are at a lower temperature. Also, the emissivity $\epsilon < 1$.

We'll look at fans next time!
